The Parents Make the Difference project in Liberia aimed to promote the development and wellbeing of young children aged 3 to 7 through reducing harsh punishment, improving parenting practices, and increasing malaria prevention behavior. The International Rescue Committee (IRC) and research partner Duke University found that caregivers reduced the use of violence and children reported increased positive parenting practices, but there was no impact on malaria prevention or early childhood development outcomes.

An estimated 200 million children under the age of five in developing countries are not meeting their developmental potential due to exposure to multiple risks including poverty, lack of nurturing and responsive care, and poor health and nutrition. Among these risk factors, harsh parenting has been consistently associated with poor cognitive, social and health outcomes during childhood and across the entire life course. Research shows that positive parenting practices and a nurturing relationship between caregiver and child can buffer the adverse effects of poverty and violence, and contribute to positive developmental outcomes. There is a strong evidence base on the effectiveness of parenting interventions in high-income countries, and an emerging body of research from low and middle-income countries suggesting that such interventions may be effective at improving parenting practices in low-resource settings. Few studies have been conducted on the impact of parenting interventions in post-conflict settings. The IRC and Duke University conducted a randomized impact evaluation of the Parents Make the Difference project in Liberia to investigate the feasibility and effectiveness of a parenting intervention at achieving multiple parenting, health, and early childhood development outcomes in a post-conflict setting.

Young children in Liberia face multiple risks to their physical, emotional and intellectual development. The majority of children growing up in Liberia experiences physical and psychological punishment, and the use of physical punishment is highly normalized among parents and caregivers in Liberia. Many children enter the formal educational system late and malaria continues to be one of the leading causes of child morbidity and mortality. In order to address these risks, the IRC implemented the Parents Make the Difference Program in Lofa County from 2012 to 2013. Lofa is located in the remote, northernmost part of Liberia and was the scene of intense fighting and widespread displacement during the civil war. The IRC has been working in Lofa since 2002 providing a range of services, including health, education, child protection and gender-based violence prevention and response.

5 National Malaria Control Program (NMCP) et al. (2012). *Liberia Malaria Indicator Survey 2011*.
Evaluation

The Parents Make the Difference program consisted of 10 weekly group sessions and 3 individual home visits. Adapted from various evidence-based parenting interventions, the program uses behavioral skills training to teach content on positive parenting, child development and malaria prevention. Session topics included: negative effects of physical and psychological punishment; positive parenting skills; how to promote children’s numeracy, vocabulary and communication skills; and malaria causes, symptoms, prevention and treatment. Facilitators conducted home visits to provide individualized support, and participants formed support groups to review program content. Intervention fidelity (i.e. facilitators’ adherence to program delivery and curriculum) was monitored by IRC technical and program staff.

The impact evaluation used a randomized waitlist controlled trial design to examine the impact of the intervention on: 1) caregivers’ parenting practices; 2) children’s cognitive, social and emotional outcomes; and 3) malaria prevention behavior. A total of 270 families participated in the impact evaluation. In addition, qualitative interviews were conducted with a subset of 30 caregivers in order to explore their experience in the program.

Results

1) The intervention was feasible and acceptable in this low-resource, post-conflict setting. Participant attendance was extremely high over the course of the program, with 98% of participants in the treatment group attending or represented by their spouse at all 10 group sessions. Almost all participants reported being “very satisfied” with the program.

2) The intervention significantly reduced the use of harsh physical and psychological punishment. Caregivers who participated in the program reported an average decrease of 25.4% in the use of harsh punishment. In particular, the occurrence of beating, whipping and spanking the child in the last four weeks decreased by 60.3%, 56.9% and 50.1% respectively. The use of psychological punishment (e.g. yelling) also decreased by 29.1%. When asked what they did the last time their child misbehaved, only 10% of caregivers in the treatment group reported beating their child compared to 44% in the control group. Qualitative findings suggest that some participants replaced harsh punishment with non-violent discipline strategies (e.g. time out) in response to new knowledge and skills they had learned through the program.

Figure 1: Impact on caregiver-reported use of harsh punishment in the last 4 weeks. Confidence intervals: 95%
3) **The intervention significantly increased caregivers’ use of positive parenting strategies, as reported by children.** Children of caregivers in the treatment group reported a significant impact on caregivers’ positive parenting practices, with an average increase of 17.9% in positive parent-child interaction such as receiving praise and spending time together. Caregivers in the treatment group reported a small, non-significant increase in positive parenting practices overall, and significant increases in the use of time out as a form of discipline and playing with their child. The ratio of negative to positive parenting practices shifted significantly away from negative practices among caregivers in the treatment group only, suggesting that when caregivers did need to discipline their children, they were more likely to choose non-violent strategies. Observation results from brief, unstructured play between caregivers and children did not reveal significant differences in the quality of caregiver-child interaction, as measured by caregiver verbalizations only.

Qualitative findings suggest that participants had more positive relationships with their children, including spending more time talking and playing together. Caregiver responses suggested that this improvement in interactions with their children stemmed from their decrease in harsh parenting behaviors, which in turn resulted in children being less fearful of and more comfortable with their caregivers. Some caregivers also reported increased recognition of their children’s physical needs and tangible improvements in the ways they provided and cared for their children, as well as being more actively involved in their children’s education.

4) **The intervention did not have an impact on children’s cognitive, emotional or behavioral outcomes.** Children of caregivers in the treatment and control groups did not differ in their performance on tests measuring verbal or numeracy skills. There were no significant differences in children’s communication behaviors or their social, emotional and behavioral outcomes.

Qualitative findings suggest that some participants observed improvements in their children’s academic motivation and achievement, and in their behavior and social and emotional wellbeing. Some participants described their children as more motivated to attend and achieve at school, more obedient and respectful, and better at social interactions with others.

5) **The intervention did not have an impact on malaria prevention outcomes.** Reported ownership and use of mosquito nets was high at baseline and post-intervention for both treatment and control groups. There was no significant increase in mosquito net ownership or use, or malaria prevention knowledge and behaviors among caregivers in the treatment group.

6) **Qualitative findings suggested potential unanticipated positive changes in participants’ families and communities.** Participants reported decreased marital conflict and improved communication and problem solving within the household. Although this was not a focus of the intervention, some respondents described how changes in their own and their spouse’s behavior (e.g. substance abuse) have resulted in improved relationships. Some participants also reported sharing what they had learned in the program with others in the community, helping to counsel other families, and serving as a role model in the community.

One of the main changes is my woman and I are not making confusion again like the way we used to make palaver [arguments] every time, and the people [facilitators] are even telling us not to be making palaver and abusing our woman because if we have confusion, our children will practice that from us.

- 47 year-old father
Lessons

1) Parenting interventions are feasible and can be delivered at low cost in resource-constrained, culturally diverse and post-conflict settings.
Implementation of the Parents Make the Difference program rural Liberia suggests that parenting interventions can be delivered at a low cost by lay facilitators, even in post-conflict contexts characterized by very limited financial and human resources. High levels of participant attendance and satisfaction also point to the cultural acceptability of the intervention. Future implementation of parenting interventions in low-resource and conflict-affected settings should ensure sufficient time and resources for training the local workforce, as well as cultural and contextual adaptation in order to maximize intervention fidelity and acceptability.

2) Brief parenting skills-building interventions can decrease caregivers’ use of violence as a form of punishment.
Our findings suggest that targeted parenting interventions of short duration can be effective at changing discipline practices and, in particular, reducing the use of violence as a form of punishment, even in contexts where such forms of punishment are highly normative. Policies and programs should shift from focusing only on awareness raising or “sensitization” activities to also include skills building interventions that equip parents and caregivers with concrete techniques they can use to manage their children’s behavior without the use of violence.

3) Further development and testing of program theory and content necessary to achieve multiple caregiver and child outcomes beyond parenting behaviors.
The study found mixed impact on positive parenting practices and caregiver-child interaction, and did not find an impact on early childhood development and malaria prevention outcomes. These results call for further development of theories of change for multi-sector interventions aimed at achieving multiple caregiver and child outcomes around violence prevention, early childhood development, education and health. Theories of change should articulate hypothesized pathways around immediate and long-term knowledge and skills acquisition, changes in attitudes and beliefs, and behavior change, which can then be tested through qualitative and quantitative methods.

4) More rigorous and longitudinal research necessary to strengthen evidence base in low-resource, post-conflict settings.
Recommendations from recent reviews of parenting interventions in low and middle-income countries as well as findings from this study point to the need for more rigorous study designs, including validation of cross-cultural measures, use of observation methods, assessment of child outcomes, and follow up of at least 12 months post-intervention to assess emergence or maintenance of longer-term outcomes. Further research is also necessary to understand the relative cost effectiveness of various intervention models, and the scalability and sustainability of interventions when delivered using a public health and social service workforce model.

The IRC is Evidence-Based and Evidence-Generating

Using findings from the Parents Make the Difference impact evaluation, the IRC is revising the intervention and improving evaluation design to address outstanding questions around the impact of parenting on child outcomes. We aim to further test the intervention through a scale up in Liberia that will reach 1,000 families, including evaluating the relative effectiveness and cost-effectiveness of parenting skills training through a group-based format only, compared with the group-based intervention plus home visits. Through the IRC’s program of research on the prevention of violence against children and youth, this study as well as research in Burundi and the Thailand-Burma border will contribute to evidence-based policy and practice around parenting and violence prevention in low-resource, conflict-affected settings.
